METABOLIC PATHWAYS

CATABOLIC PATHWAYS

ANABOLIC PATHWAYS

Are involved in oxidative breakdown of larger complexes.

They are usually **exergonic** in nature

Are involved in the synthesis of compounds.

They are usually endergonic in nature.

CHARACTERISTICS OF METABOLISM

- 1. Metabolic pathways are mostly irreversible
- Every metabolic pathway has a committed first step.
- 3. All metabolic pathways are regulated.
- Metabolic pathways in eukaryotic cells occur in specific cellular locations.

GLYCOLYSIS

GLYCOLYSIS

Glycolysis comes from a merger of two Greek words:

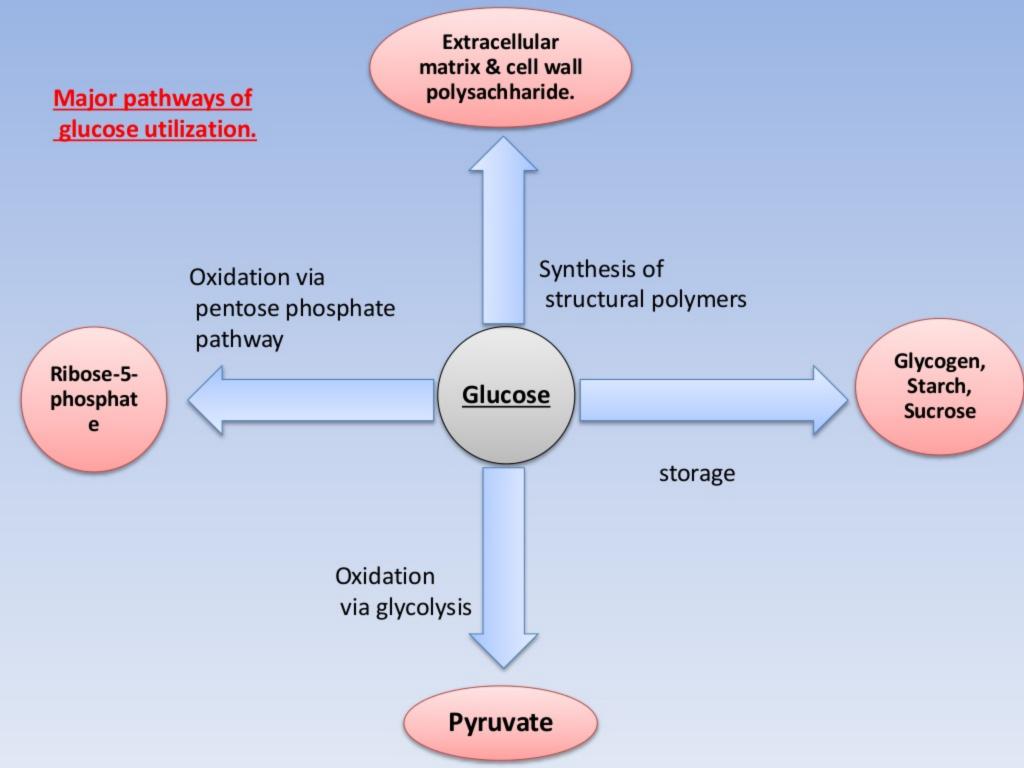

- ➢ Glykys = sweet
- Lysis = breakdown/splitting

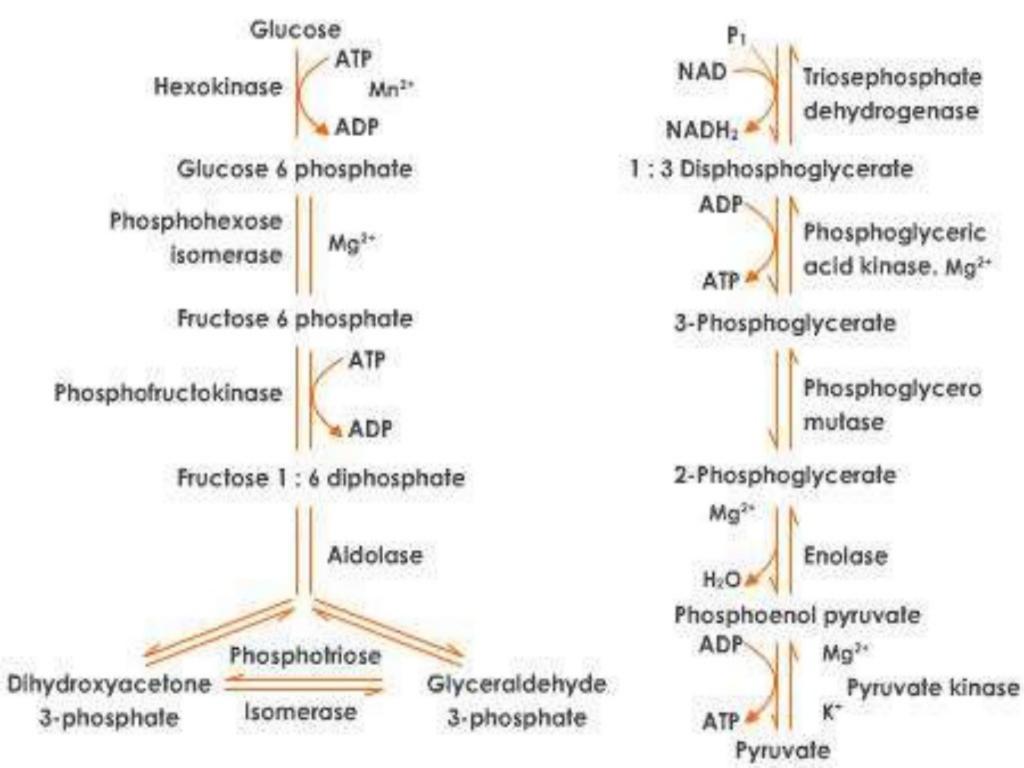

It is also known as Embden-Meyerhof-Parnas pathway or EMP pathway.

INTRODUCTION

- GLYCOLYSIS is the sequence of 10 enzyme-catalyzed reactions that converts glucose into pyruvate with simultaneous production on of ATP.
- In this oxidative process, 1mol of glucose is partially oxidised to 2 moles of pyruvate.
- This major pathway of glucose metabolism occurs in the cytosol of all cell.
- This unique pathway occurs aerobically as well as anaerobically & doesn't involve molecular oxygen.

- It also includes formation of Lactate from Pyruvate.
- The glycolytic sequence of reactions differ from species to species only in the mechanism of its regulation & in the subsequent metabolic fate of the pyruvate formed.
- In aerobic organisms, glycolysis is the prelude to Citric acid cycle and ETC.
- Glycolysis is the central pathway for Glucose catabolism.

TWO PHASES OF GLYCOLYSIS

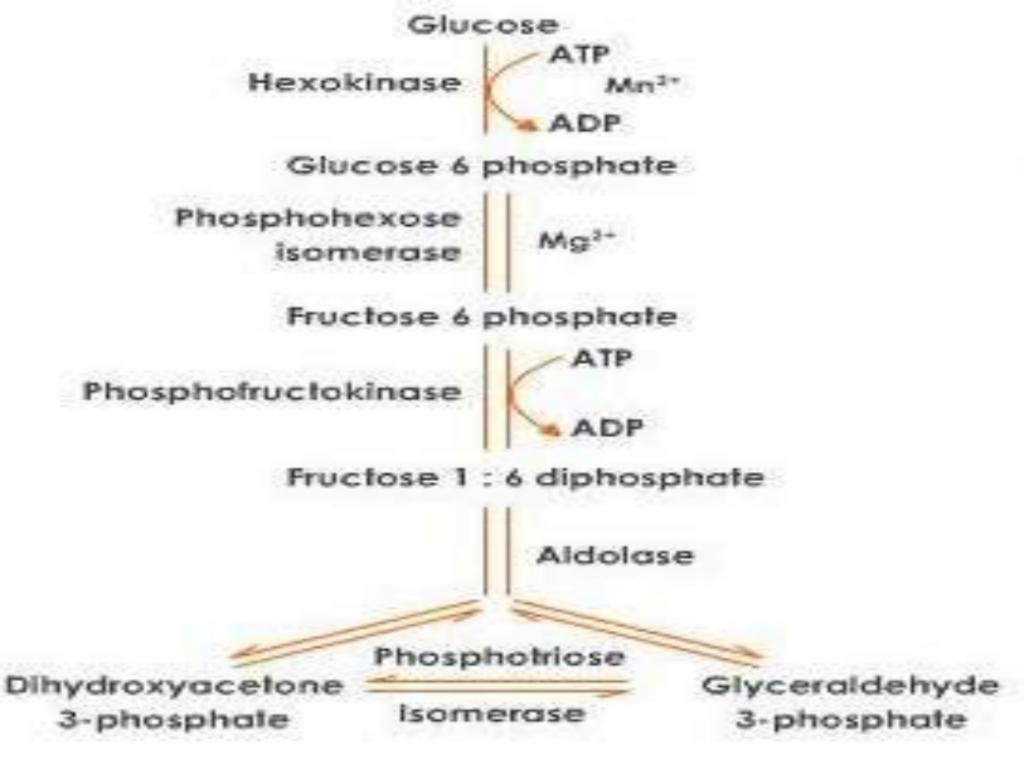

- Glycolysis leads to breakdown of 6-C glucose into two molecules of 3-C pyruvate with the enzyme catalyzed reactions being bifurcated or categorized into 2 phases:
- 1. Phase 1- preparatory phase
- 2. Phase 2- payoff phase.

PREPARATORY PHASE

- It consists of the 1st 5 steps of glycolysis in which the glucose is enzymatically phosphorylated by ATP to yield Fructose-1,6-biphosphate.
- This fructuse-1,6-biphosphate is then split in half to yield 2 molecules of 3-carbon containing Glyceraldehyde-3-phosphate/ dihyroxyacteone phosphate.

 Thus the first phase results in cleavage of the hexose chain.

 This cleavage requires an investment of 2 ATP molecules to activate the glucose mole and prepare it for its cleavage into 3-carbon compound.

PAYOFF PHASE

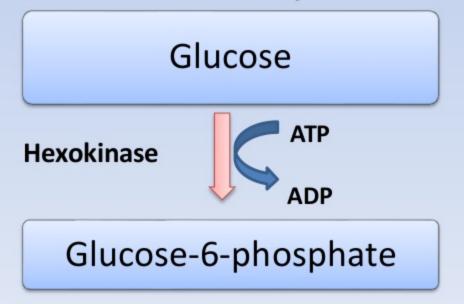

- This phase constitutes the last 5 reactions of Glycolysis.
- This phase marks the release of ATP molecules during conversion of Glyceraldehyde-3-phosphtae to 2 moles of Pyruvate.
- Here 4 moles of ADP are phosphorylated to ATP.
 Although 4 moles of ATP are formed, the net result is only 2 moles of ATP per mole of Glucose oxidized, since 2 moles of ATP are utilized in Phase 1.

STEPWISE EXPLAINATION OF GLYCOLYSIS

STEP 1: PHOSPHORYLATION

- Glucose is phosphorylated by ATP to form sugar phosphate.
- This is an irreversible reaction & is catalyzed by hexokinase.
- Thus the reaction can be represented as follows:

STEP 2: ISOMERIZATION

- It is a reversible rearrangement of chemical structure of carbonyl oxygen from C1 to C2, forming a Ketose from the Aldose.
- Thus, isomerization of the aldose Glucose6-phosphate gives the ketose, Fructose-6-phosphate.

Glucose-6-phosphate

Phosphoglucoisomerase

Fructose-6-phosphate

STEP 3: PHOPHORYLATION

- Here the Fructose-6-phosphate is phosphorylated by ATP to fructose-1,6-bisphosphate.
- This is an irreversible reaction and is catalyzed by phosphofructokinase enzyme.

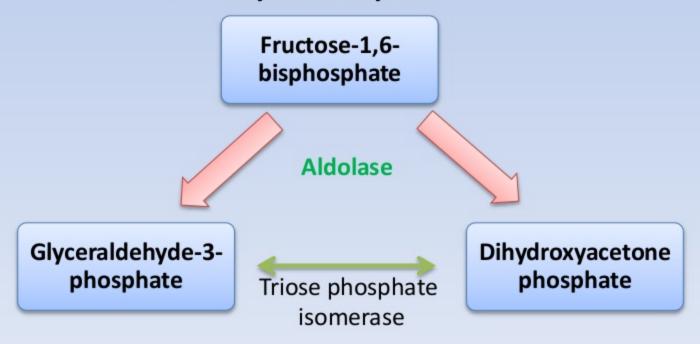

Fructose-6-phosphate

Phosphofructokinase ADP

Fructose-1,6-bisphosphate

STEP 4: BREAKDOWN

- This six carbon sugar is cleaved to produce two 3-C molecules: glyceradldehyde-3-phosphate (GAP) & dihydroxyacetone phosphate(DHAP).
- This reaction is catalyzed by Aldolase.

STEP 5: ISOMERIZATION

- Dihydroxyacetone phosphate is oxidized to form Glyceraldehyde-3-phosphate.
- This reaction is catalyzed by triose phosphate isomerase enzyme.

2 Glyceraldehyde-3-phosphate

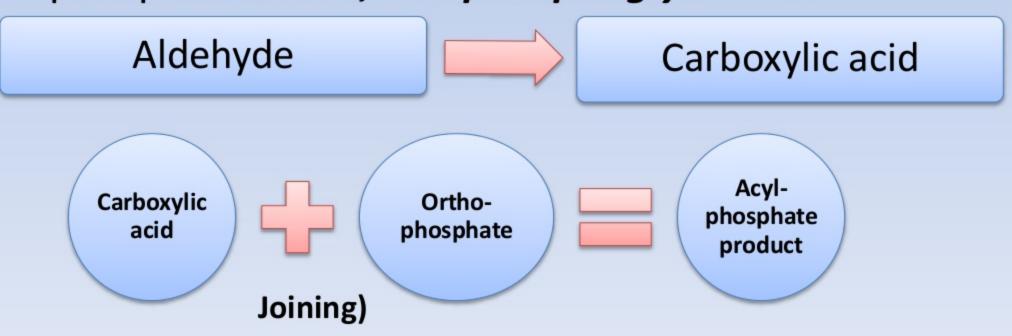

Triose phosphate isomerase

Dihydroxyacetone phosphate

STEP 6

- 2 molecules of Glyceraldehyde-3-phosphate are oxidized.
- Glyceraldehyde-3-phosphate dehydrogenase catalyzes the conversion of Glyceraldehyde3phosphate into 1,3-bisphosphoglycerate.

Resultant reaction

2

Glyceraldehyde-3-phosphate

Glyceraldehyde-3-phosphate dehydrogenase

2NAD+ + 2Pi
2NAD+ + 2Pi
2NADH + 2H+

2

1,3-bisphosphoglycerate

STEP 7

- The transfer of high-energy phosphate group that was generated earlier to ADP, form ATP.
- This phosphorylation i.e. addition of phosphate to ADP to give ATP is termed as substrate level phosphorylation as the phosphate donor is the substrate 1,3-bisphosphoglycerate (1,3-BPG).
- The product of this reaction is 2 molecules of 3-phosphoglycerate.

1,3-bisphosphoglycerate

Phosphoglycerate kinase

2 ADP

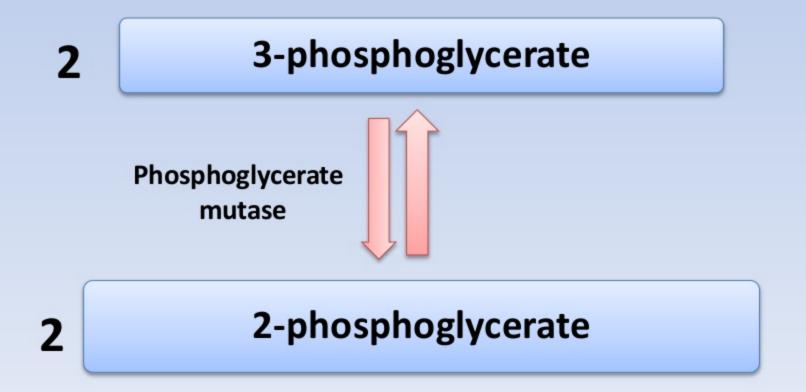

FIRST SUBSTRATE LEVEL PHOSPHORYLATION

2 ATP

3-phosphoglycerate

STEP 8

 The remaining phosphate-ester linkage in 3phosphoglycerate, is moved from carbon 3 to carbon 2 ,because of relatively low free energy of hydrolysis, to form 2-phosphoglycerate(2-PG).

STEP 9: DEHYDRATION OF 2-PG

- This is the second reaction in glycolysis where a high-energy phosphate compound is formed.
- The 2-phosphoglycerate is dehydrated by the action of enolase to phosphoenolpyruvate(PEP). This compound is the phosphate ester of the enol tautomer of pyruvate.
- This is a reversible reaction.

2-phosphoglycerate

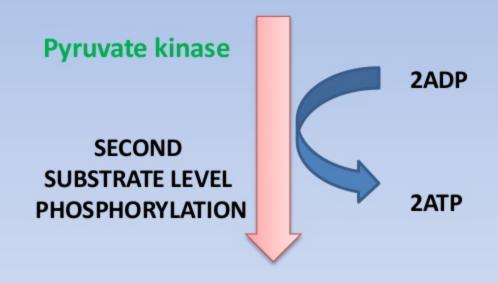

Phosphoenol pyruvate

STEP 10: TRANSFER OF PHOSPHATE FROM PEP to ADP

- This last step is the irreversible transfer of high energy phosphoryl group from phosphoenolpuruvate to ADP.
- This reaction is catalyzed by pyruvate kinase.
- This is the 2nd substrate level phosphorylation reaction in glycolysis which yields ATP.
- This is a non-oxidative phosphorylation reaction.

Phosphoenolpyruvate

2

Pyruvate

OVERALL BALANCE SHEET OF GLYCOLYSIS

 Each molecule of glucose gives 2 molecules of Glyceraldehyde-3-phosphate. Therefore, the total input of all 10 reactions can be summarized as:

Glucose + 2ATP+ 2Pi+ 2NAD+ 2H+ 4ADP

2Pyruvate+ 2H++ 4ATP+ 2H2O+ 2NADH+ 2ADP

On cancelling the common terms from the above equation, we get the net equation for Glycolysis:

Glucose+ 2Pi+ 2ADP+ 2NAD+

2Pyruvate+ 2NADH+ 2ATP+ 2H⁺ + 2H₂O

THUS THE SIMULTANEOUS REACTIONS INVOLVED IN GLYCOLYSIS ARE:

- ➤ Glucose is oxidized to Pyruvate
- > NAD+ is reduced to NADH
- > ADP is phosphorylated to ATP

• ENERGY YIELD IN GLYCOLYSIS:

STEP NO.	REACTION	CONSUMPTION OF AIP	GAIN OT AIP
1	Glucose glucose-6-phosphate	1	-
3	Fructose-6-phosphate fructose-1,6-biphosphate	1	-
7	1,3-diphosphoglycerate 3-phosphoglycerate	-	1x2=2
10	Phosphoenolpyruvate> pyruvate	-	1x2=2
		2	4
		Net gain of ATP=4-2= 2	

-- REGULATION OF GLYCOLYSIS --

Three irreversible kinase reactions primarily drive glycolysis forward.

- hexokinase or glucokinase
- phosphofructokinase
- pyruvate kinase

Three of these enzymes regulate glycolysis as well.

2. HEXOKINASE

Phosphorylation of glucose.

◆Inhibited by its product, glucose 6-phosphate, as a response to slowing of glycolysis

Not GLUCOKINASE - as discussed

2. PHOSPHOFRUCTOKINASE

- major regulatory enzyme, rate limiting for glycolysis
- an allosteric regulatory enzyme.
- measures adequacy of energy levels. Inhibitors: ATP by decreasing fructose 6-phosphate binding and citrate both indicate high energy availability
- Activators: ADP, AMP, low energy

AMP and ADP reverse ATP inhibition

And another activator

Fructose 2,6 bisphosphate is a very important regulator, controlling the relative flux of carbon through glycolysis versus gluconeogenesis.

- It also couples these pathways to hormonal regulation.

3. **PYRUVATE KINASE** PEP + ADP→ pyruvate + ATP

- An allosteric tetramer
- inhibitor: ATP
- inhibitors: acetyl CoA and fatty acids (alternative fuels for TCA cycle)
- **♦ activator:** fructose 1,6-bisphosphate ("feed-forward")

- Phosphorylation (inactive form) and dephosphorylation (active form) under hormone control.
- Also highly regulated at the level of gene expression ("carbohydrate loading")
